Supplementary Methods

Datasets

Clinical and prescription NHS data (primary care general practice (GP) datasets, data providers TPP (<https://www.tpp-uk.com/>) and EMIS (<https://www.emishealth.com/>) were retrieved on Oct. 1st, 2021. Codes for diabetes diagnosis and anti-diabetic medication prescriptions were obtained from using SNOMED (EMIS dataset), CTV3 and TPP local codes (TPP dataset). Only participants with clinical data and prescription data were included in the study, under the assumption that the data for the other participants was not available, rather than that these individuals never sought NHS services.

The fields from UK Biobank data download (retrieved on Oct 1st, 2021) used for this analysis were: '53-0.0' Date of Recruitment, '21022-0.0' Age at Recruitment, '34-0.0' Year of birth, '52-0.0' Month of Birth, '40007-0.0' Age at Death, '40000-0.0' Date of Death, '40001-0.0' Cause of Death, '31-0.0' Sex, '22009-0.1' to '22009-0.10' Genetic principal components (PC) 1-10, '22040-0.0' Summed MET minutes per week for all activity, 21001-0.0 BMI, '189-0.0' Townsend deprivation index, '20161-0.0' PackYears, '20116-0.0' Smoking status, '1160-0.0' Sleep duration, '2453-0.0' Cancer diagnosed by doctor, '2463-0.0' Fractured/broken bones in last 5 years, '2473-0.0' Other serious medical condition/disability diagnosed by doctor, '6150-0.0' Vascular/heart problems diagnosed by doctor.

The British National Formulary (BNF) and ATC codes were used to annotate T2D treatments. In particular, we BNF codes 6.1.1 – ‘Insulin’ and 6.1.2 ‘Antidiabetic drugs’ within the broad category “Drugs used in Diabetes” were used to select for prescriptions of antidiabetic medications. ATC10 4th level super-codes A10A - ‘INSULINS AND ANALOGUES’ and A10B - BLOOD GLUCOSE LOWERING DRUGS, EXCL. INSULINS in the broad category “Drugs used in Diabetes”) were used to subdivide the non-insulin antidiabetic drugs (A10B) into functional classes, which are the ones used for the classification in this manuscript, if they reached a critical number of prescribed patients. In particular:

- o A10BA Biguanides;
- o A10BB Sulfonylureas;
- o A10BF Alpha glucosidase inhibitors or acarbose – present in the dataset, but in low numbers and therefore excluded from the study;
- o A10BG Thiazolidinediones;
- o A10BH Dipeptidyl peptidase 4 (DPP-4) inhibitors;
- o A10BJ Glucagon-like peptide-1 (GLP-1) analogues;
- o A10BK Sodium-glucose co-transporter 2 (SGLT2) inhibitors;
- o A10BX Other blood glucose lowering drugs, excl. insulins – in this category there are meglitinides present in the dataset, but in low numbers and therefore excluded from the study.

The categories: A10BC Sulfonamides (heterocyclic) were not found among NHS prescriptions, and A10BD Combinations of oral blood glucose lowering drugs were subdivided into individual components.

Criteria for Inclusion and Exclusion of Participants

Individuals that had not taken anti-diabetic medications for at least three consecutive months, and that were not taking these medications within six months of the last recorded event (either death or last censoring), were not considered users of that medication. Individuals with missing values for the covariates analysed were eliminated from the analysis.

Observation Time, Length of Exposure, and End Points

The data on deaths was available for all individuals as linked to the national death registry, updated every six or three months (<https://biobank.ndph.ox.ac.uk/showcase/ukb/docs/DeathLinkage.pdf>), and the last recorded date of death (anteceding the date of data retrieval of more than six months) was chosen as the day of censoring to ensure completeness of the death registry data.

For the T2D with drug vs T2D without drug matching strategy (see below), the age at first drug was included in the covariates to match, to avoid immortal time bias¹. By matching each patient by age at recruitment and age at first drug use, we ensured that the length of exposure to the target drug treatment was the same as the control drug.

Survival Analyses: General Remarks

The day of birth is not available for privacy and data protection regulations, therefore the precise age of the participant at the age of recruitment was estimated, taking into account the age between date of birth (DOB) and date of recruitment, assuming that the DOB is on the 15th of the month². This was not the case for 4520 participants, whose birthday was between the beginning

of the month and the recruitment date before the 15th of the month. For these participants the estimated age was rounded up to the declared age of recruitment. In the dataset used for these analyses (retrieved on Oct 1st, 2021) is the date of the last reported death, therefore that was considered the time of censoring and used to calculate the inferred age of the live participants from the estimated age at recruitment². The inferred age at death was calculated from the estimated age at recruitment and the date of death. The censoring status = 1 indicates that an event occurred (i.e., death), status = 0 indicates that the observation was right censored (i.e., participant was alive at the time of censoring; March 20th, 2021).

Survival Analyses of Observational Cohort

In Kaplan-Meier survival estimates, the entire cohort was subdivided into non-T2D-diagnosed and T2D-diagnosed, or into non-T2D-diagnosed, T2D-diagnosed taking the drug of interest or T2D-diagnosed not taking the drug of interest (**Fig. 1b**). The survival probability of each group is expressed as proportion of individuals that are alive at that age versus total number of individuals that have died at that age³. P values shown were calculated with log-rank test.

Multivariate analysis of survival was analysed with Cox proportional-hazard regression model (**Fig. 1c**). Proportional hazard assumption was checked and it was met for all covariates. The difference between the age of recruitment and the age of last censoring was the survival time of the model.⁴ Age at recruitment, sex, genetic principal components 1-20 (as proxy for population ethnic diversity), lifestyle factors (BMI, smoking, alcohol intake, physical exercise, Townsend deprivation index, sleep duration), comorbidities (Fractured/Broken Bones, Cancer, Cardiovascular disease, Blood Clots, DVT, Bronchitis, Emphysema, Other serious medical condition), and Use of Anti-Diabetic Drugs, were covariates of the model.

Nearest Neighbour Covariate Matching (NNCM) Strategy

(i) Introduction

We opted to individually match the users of each drug to control individuals with similar characteristics to evaluate the effect of the target drug with minimal confounding on outcomes. Individual matching, differently from frequency-based matching which selects controls based on similar distribution of variables, ensures that treated individuals and their respective controls are selected based on the exact matching of selected features, and resembles as closely as possible a randomised clinical trial⁵. Among the available algorithms developed for individual matching⁶⁻⁷, we opted to use a previously established nearest neighbours algorithm-based strategy⁶⁻⁸ based on data-driven covariate-specific distance metrics (**Fig. S5a-b**). This method has greater power in dealing with non-homogenous cohorts, such as the ones we have (**Fig. S6**), and provided the most accurate matching for covariates heavily responsible for outcomes.

With a data-driven approach based on a Cox proportional hazard model, we selected for each cohort covariates that mostly affect longevity, called priority-matched covariates (**Fig. S5a-d**), and thanks to *ad hoc* distance metrics, they were the ones contributing mostly for the matching (**Fig. S5e-f**). This ensured that priority-matched covariates were matched most accurately to minimise the differences among individuals mostly contributing to age at death. In the first analysis, we compared T2D individuals who were either taking the drug of interest (and potentially other drugs) with matched controls who were T2D-diagnosed and using another anti-diabetic drug (or multiple other drugs), while in the second analysis, we compared T2D individuals who were taking the drug with control individuals that were not T2D-diagnosed (non-T2Ds).

(ii) Matching Algorithm

For each individual diagnosed with T2D treated with the drug of interest (T2D with drug) the unsupervised nearest neighbours algorithm (adapted from the Python library scikit-learn 1.0.2 NearestNeighbors) would assign one individual from T2D subjects not taking that drug (T2D without drug) or from the non-T2D-diagnosed subjects cohort (non T2D without drug) with the smallest cumulative covariate distance (computed *ad hoc* as explained below). Males and females were matched separately, to ensure precise matching of the sex. If more than one patient matched to the same control individual, the matching was reassigned to ensure univocal 1:1 matching. The cumulative covariate distance was calculated by assigning a custom distance metric according to their data type and priority level (**Fig. S5**).

(iii) Data-driven Selection of Priority-matched Covariates

A Cox proportional hazard multivariate model was used to determine within each cohort comparison the covariates contributing mostly to the observed mortality (having $\log(\text{HR}) > 0.05$ or $\log(\text{HR}) < -0.05$), hereafter referred to as priority-matched covariates (**Fig. S5a-b and 5c-d**).

The priority-matched covariates were assigned an exponentially growing distance weight if differing between individuals more than one standard deviation or more than one mismatched comorbidity. The other covariates, including use of additional anti-diabetic drugs and age at first use of the anti-diabetic drug of interest to estimate exposure, were assigned a Euclidean distance, if continuous, or a Hamming distance, if binary.

(iv) Ad hoc Distance Metrics for Priority-matched Covariates and Other Distance Metrics

To match treated and control individuals, we calculated how different each pair of treated and control individuals was, and for each treated individual we took the most similar control individual, without using the same control individual twice. To calculate how different each treated-control pair was, we created an algorithm that assessed how distant the covariates of each individuals were. Novel sets of metrics, named here *ad hoc* distance metrics, were created to establish the cumulative distance between covariates of treated and control individuals. These *ad hoc* distances were devised to increase exponentially if two covariates were differing more than one standard deviation (if quantitative such as age) or of more than one yes/no answer in morbidity status (the binary covariates). In this way, the likelihood of matching very distant individuals was very low. More in detail, distance between priority-matched rescaled (mean = 0, standard deviation = 1) quantitative covariates (Age at recruitment) was determined as a distance that would exponentially increase for differences in the covariates greater than 0.1 standard deviations

with the formula $e^{\frac{(x_{T2D+drug} - x_{control})^2}{0.1^2}} - 1$ (where $x_{T2D+drug}$ and $x_{control}$ are respectively the covariate values for each treated-control pair) (**Fig. S5e**). Distance between priority-matched binary covariates (cancer, cardiovascular, etc.) was coded as a distance that would exponentially increase for cumulative Hamming distances greater than 1, and calculated with the formula $e^{\sum_{i=0}^n |x_{i(T2D+drug)} - x_{i(control)}|} - 1$ (where $x_{i(T2D+drug)}$ and $x_{i(control)}$ are the treated-control pair values of the i th binary priority-matched covariate) (**Fig. S5f**). This strategy ensures that each matched individual is allowed to differ by at most one mismatched priority-matched diagnoses, otherwise the distance becomes exponentially big. Distances between other quantitative covariates used for matching were calculated as Euclidean distances, while for binary covariates as Hamming distances (**Fig. S5**).

Individuals with T2D which are not prescribed the drug of interest (the control group to individuals with T2D using the drug of interest) take any other antidiabetic drug which is not the drug of

interest. Therefore, for the T2D with drug vs T2D without drug matching strategy, the age at first drug was included in the covariates to match, to avoid immortal time bias.¹ By matching each patient by age at recruitment and age at first drug use (either drug of interest or any other antidiabetic drug in the control group), we ensured that the length of exposure to the target drug treatment was the same as the control drug.

(v) *Cohorts Homogeneity after NNCM*

The matching strategy used ensured that the average standardised mean difference of all covariates within the treated and matched cohort was below 5%. All treated individuals were matched to untreated controls, excluding individuals who did not have data for the features used for matching.

Survival Analyses of NNCM Cohorts

For each drug, survival analysis was performed between T2D with drug vs T2D without drug NNCM Cohorts (**Fig. 2a-b**) or between T2D with drug vs non-T2D without drug NNCM Cohorts (**Fig. 3a-b**), or between T2D with DPP4I/SGLT2I with metformin vs T2D with metformin only vs non-T2D without drug NNCM Cohorts (**Fig. 4a-b**), survival analyses were performed as in the observational cohort, with the difference that the analysis of NNCM cohorts T2D with drug and T2D without drug (**Fig. 3a-b**), the use of other diabetic drugs, as well as the age at first use (to take into account exposure time) were added as exogenous variables, while in T2D with DPP4I/SGLT2I with metformin vs T2D with metformin only vs non-T2D without drug NNCM Cohorts (**Fig. 4a-b**) age at first use was added as exogenous variable.

Statistical Analyses

All the analyses, figures and tables were created with Python3.7 using the following libraries: pandas v.1.1.4, matplotlib v.3.3.4, seaborn v. 0.11.1, scipy v. 1.4.1, sklearn v.0.0, statsmodels v. 0.11.0, numpy v.1.19.5, and lifelines v.0.25.11 (<https://doi.org/10.21105/joss.01317>)

Survival curves were generated with the Python 3.7 and Lifelines (lifelines v.0.25.11) package KaplanMeierFitter function, and P-values calculated with log-rank test (lifelines v.0.25.11). Multivariate analysis of survival was analysed with Cox proportional-hazard regression model using lifelines v.0.25.11 CoxPHFitter. Proportional hazard assumption was checked with lifelines v.0.25.11 function *check_assumption* and it was met for all covariates. Aberrations from the proportion of expected versus observed deaths of a certain cause within the case-control cohorts were calculated with a chi-squared test (scipy v. 1.4.1).

Supplementary Table 2

Absolute number and percentage of deaths agglomerated as ICD10 codes level 3 in each cohort of T2D using each selected drug and matched T2D individuals. P values obtained by chi-squared contingency test.

Metformin

Causes of death	Number of Deaths in T2D matched controls	Percentage of Deaths in T2D matched controls	Number of Deaths in Metformin users	Percentage of Deaths in Metformin users	p-value
